

To read a switch, you must assign the corresponding port pin as input then read the states of that pin, it will be either on (1) or off (0)

Here is a code example

```
void main() {  
  
    Trisb=0b000001101;  
    Portb=0;  
    //Trisb.F0=1;  
    //trisb.F1=0;  
    //portb.F1=1;  
  
    portb.F1=1;  
    delay_ms(500);  
    portb.F1=0;  
    delay_ms(500);  
  
    while(1){  
        if(portb.F0==0){ /// check pin state to know if the switch is clicked or not  
            portb.F1=1;  
            delay_ms(500);  
            portb.F1=0;  
            delay_ms(500);  
        }  
    }  
}
```

Two push buttons

```
int flag;  
  
void main() {  
    Trisb=0b000000101;  
    Portb=0X00;  
  
    while(1){  
        if(portb.F0==0 || flag==1){  
            Portb.F1=1;  
            flag=1;  
        }  
  
        if(portb.F2==1 || flag==0){  
            Portb.F1=0;  
            flag=0;  
        }  
        delay_ms(100);  
    }  
}
```

Using one push button to turn a led on and off

```
int flag;
void main() {
    trisb=0b000000101;
    portb=0x00;

    while(1){

        if(portb.f2==1){
            portb.f1=1;
            flag=1;
            delay_ms(100);
        }

        if(portb.f2==1){
            delay_ms(100);
            if(portb.f2==0 && flag==1){
                portb.f1=0;
                flag=0;
                delay_ms(100);
            }
        }

    }
}
```
